

Vietnam : Développement de l'aquaculture durable

High global demand for seafood and unsustainable fishing methods are dwindling aquatic resources. Destructive fishing methods, which are still rampant in some parts of the Asia Pacific, are rapidly destroying coral reef ecosystems.

Without urgent measures from fishing companies, seafood importers, and consumers, fish stocks will continue to decline and we may not have enough fish resources left in the near future to secure food and the livelihoods of those in the industry, said a representative of Worldwide Fund for Nature (WWF) in Vietnam.
